

1. The following regression output is for predicting annual murders per million from the percentage of citizens living in poverty in a random sample of 20 metropolitan areas.

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	-29.901	7.789	-3.839	0.001
poverty%	2.559	0.390	6.562	0.000

$$s = 5.512$$

$$R^2 = 70.52\%$$

$$R_{adj}^2 = 68.89\%$$

- (a) Write out the linear model.

**Solution:**  $\hat{y}_i = -29.901 + 2.559x_i$

- (b) Interpret the slope.

**Solution:** For every additional percentage of citizens living in poverty there is an associated 2.559 increase in murders per million.

- (c) Interpret  $R^2$ .

**Solution:** There is good predictive power. 70.52 percent of the variation in annual murders per million can be explained by the percentage of citizens living in poverty.

- (d) Calculate the correlation coefficient.

**Solution:**  $r = \sqrt{R^2} = \sqrt{.7052} = .8398$

- (e) Interpret the correlation coefficient.

**Solution:** There is a strong positive linear relationship between the percentage of citizens living in poverty and the number of annual murders per million.

- (f) Predict the number of murders per million if one city has a 14% of its citizens living in poverty.

**Solution:**  $\hat{y}_i = -29.901 + 2.559(14) = 5.926$

- (g) After a few months, the city with 14% of its citizens living in poverty reported the number of murders per million was 4.773. Calculate the residual for this city's reported murder rate.

**Solution:**  $e_i = y_i - \hat{y}_i = 4.773 - 5.926 = -1.153$

2. A regression line relating  $y$  = hours of sleep the previous day to  $x$  = hours studied the previous day is estimated using data from  $n = 10$  students. The estimated slope  $\beta_1 = -0.30$ . The standard error of the slope is 0.20.

(a) What is the value of the test statistic for the following hypothesis test about , the population slope?

$$H_o: \beta_1 = 0$$

$$H_a: \beta_1 \neq 0$$

$$\textbf{Solution: } t = \frac{\hat{\beta}_1 - 0}{SE_{\hat{\beta}_1}} = \frac{-0.30 - 0}{0.20} = -1.5$$

(b) At the  $\alpha = 0.10$  level, would you reject the null hypothesis? State your conclusion in terms of the problem.

$$\textbf{Solution: } d.f. = n - (k + 1) = 8$$

$$t_c = -1.860$$

We fail to reject the null hypothesis and conclude the alternative is not true. There is not a linear relationship between hours studied the previous day, and the hours of sleep the previous day.

(c) What is a 90% confidence interval for  $\beta_1$ , the population slope? Interpret the confidence interval you calculate.

**Solution:** C.I. = (-0.67, 0.07) We are 90% confident that a one hour increase in hours studied the previous day is associated with somewhere between 0.67 decrease and 0.07 increase in hours of sleep the previous day.
